Featured Research from universities, journals, and other organizations Mechanical properties of polymeric nanocomposites Date: November 14, 2013 Source: University of Michigan Summary: Polymer nanocomposites may prove useful in a number of applications, including as structural materials for aircraft or other structures. Because the interface between the polymer and the inorganic material can have a significant effect on the properties of the composite, it is important to understand how the interface properties are controlled. In the work described by researchers in the University of Michigan's College of Engineering, scientists used mechanical testing to measure the mechanical properties of two forms of polymeric nanocomposites, including composite films and nanocomposite polymers. Share This Chemistry professor Michael McAlpine and post-doctoral researcher Tatyana Kazakov use micro-indentation to measure the mechanical properties of polymer nanocomposites. Related Articles In the first part of the study, published in the journal MRS Bulletin, U-M researchers measured the mechanical properties of a monolithic copolymer composite. The monolithic copolymer material is comprised of poly(3-phenylthiophene) (P3TP) segments and poly(3-hexylthiophene) (P3HT) segments. The P3TP material has a block-like structure, where the P3HT segments are arranged in a rod-like form. In monolithic P3TP-P3HT the P3HT segments are actually embedded in the P3TP, which affects the macroscopic properties of the composite material. On the other hand, when P3TP segments are isolated, creating nanocomposite P3TP, the P3HT segments would be exposed to the P3TP segments, resulting in a new, unique material. The P3HT nanocomposite is different from the

Synthesis and pharmacological activity of 1-(1,4-dihydronaphthyl-4-oxo)-4-phenylpiperazines and their 1-O-alkyl derivatives. 1-(1,4-Dihydronaphthyl-4-oxo)-4-phenylpiperazines having a relatively high beta-blocking activity have been synthesized. All the compounds showed an interesting ratio of beta- and alpha-adrenoceptor-blocking activity, in particular the 1-(1,4-dihydronaphthyl-4-oxo)-2-isopropyl-4-phenylpiperazine 7p) showed a ratio of 40/60, so we could consider its low toxicity. Compound 7p exhibited its intrinsic cardioselectivity. The complete pharmacological data obtained in bioassays support its cardioselective properties. Example: `string Data[4]; Data[0] = "Hi"; Data[1] = "Hello"; Data[2] = "Bye"; Data[3] = "World";` What this above code snippet does is assign "Hi" to the 1st string pointer, "Hello" to the 2nd string pointer, "Bye" to the 3rd string pointer and "World" to the 4th pointer. What I would want to do is to dynamically create my string array. ie; `string Data[4] = { "Hello", "Bye", "World" };` So that when I access the first string, "Hello" via the pointer `Data[0]` it would point to the string "Hello" in the Data array. Any idea how this can be done in C++? A:
